# Recall: Scalar quantization

$$Q : x \in \mathbb{R} \rightarrow y \in \mathcal{C} = \{\hat{x}_1, \hat{x}_2, \dots, \hat{x}_L\} \subset \mathbb{R}$$

# Uniform Quantization

- ▶ Simple
- ▶ Minimize maximum error
- ▶ Optimal for uniform random variables (RV's)

RD curve for UQ of uniform RV:

$$D = \sigma_X^2 2^{-2R}$$

RD curve for UQ of non-uniform RV in *high resolution*:

$$D = K_X \sigma_X^2 2^{-2R}$$

# Uniform Quantization

## Example

Image Originale, 24 bpp

# Uniform Quantization

## Example

# Uniform Quantization

## Example

Débit 3 bpp   PSNR 25.75 dB   TC 8.000

# Quantization

## Conclusion

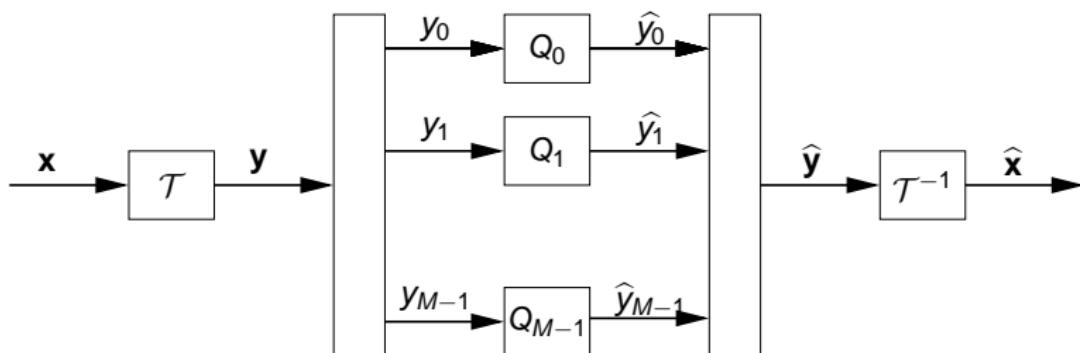

- ▶ Quantization: at the core of lossy coding
- ▶ Irreversible operation
- ▶ Central in the rate-distortion trade-off
- ▶ Approximations in HR:
  - ▶  $D \sim 2^{-2R}$
  - ▶  $D \sim \sigma^2$
- ▶ Quantization alone is not sufficient to give good RD performance

# Linear transform

- ▶ Linear transform is a base changement
  - ▶ Separation of data between important and irrelevant (energy concentration)
  - ▶ HSV relevant information
  - ▶ Resource allocation
- ▶ Correlation reduction

# Linear transform

Paradigm of transform coding

From  $\mathbf{x}$  to  $\mathbf{y} = \mathcal{T}\mathbf{x}$  : we want an “easier” vector for coding, i.e. with a few large coefficients and many small ones

# Orthogonal Transformas

It means that  $\mathcal{T}^{-1} = \mathcal{T}^T$

advantages :

1. immediate inversion
2. norm conservation  $\|\mathbf{Y}\| = \|\mathbf{X}\|$

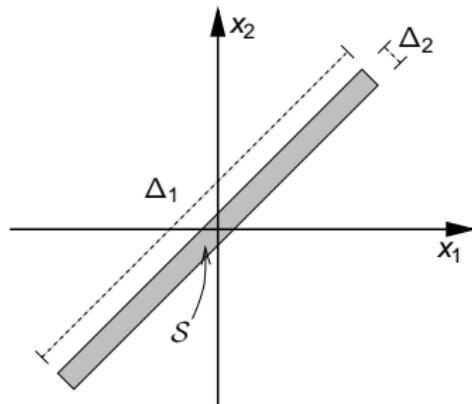

⇒ Distortion on  $\mathbf{Y}$  = distortion on  $\mathbf{X}$  :

$$\begin{aligned} E \left[ \|\mathbf{Y} - \hat{\mathbf{Y}}\|^2 \right] &= E \left[ (\mathbf{Y} - \hat{\mathbf{Y}})^T (\mathbf{Y} - \hat{\mathbf{Y}}) \right] = E \left[ (\mathbf{X} - \hat{\mathbf{X}})^T \mathcal{T}^T \mathcal{T} (\mathbf{X} - \hat{\mathbf{X}}) \right] \\ &= E \left[ \|\mathbf{X} - \hat{\mathbf{X}}\|^2 \right] \end{aligned}$$

# Transform coding

## Example

Couple of highly correlated RV's

$$f_{X_1, X_2}(x_1, x_2) = \begin{cases} \frac{1}{\Delta_1 \Delta_2} & \text{if } (x_1, x_2) \in S \\ 0 & \text{if } (x_1, x_2) \notin S \end{cases}$$

$$\Delta_1 \gg \Delta_2$$

$$X_1 \sim X_2 \sim \mathcal{U}\left[-\frac{\Delta_1}{2\sqrt{2}}, \frac{\Delta_1}{2\sqrt{2}}\right]$$

# Transform coding

## Example

- ▶ Quantization of uniform variables  $\Rightarrow$  UQ
- ▶  $D_i(R_i) = \sigma_i^2 2^{-2R_i}$  for each RV
- ▶  $D = \sum_i D_i$
- ▶  $\sigma_1^2 = \sigma_2^2 = \sigma^2 = \left(\frac{\Delta_1}{\sqrt{2}}\right)^2 \frac{1}{12} = \frac{\Delta_1^2}{24}$

# Transform coding

## Example

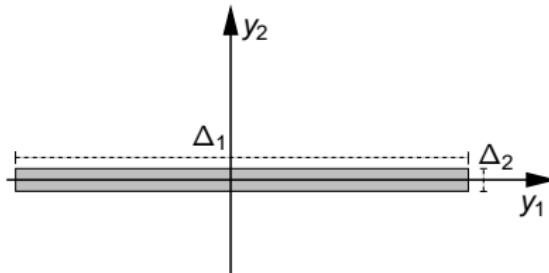

- ▶ Quantization of uniform variables  $\Rightarrow$  UQ
- ▶  $D_i(R_i) = \sigma_i^2 2^{-2R_i}$  for each RV
- ▶  $D = \sum_i D_i$
- ▶  $\sigma_1^2 = \sigma_2^2 = \sigma^2 = \left(\frac{\Delta_1}{\sqrt{2}}\right)^2 \frac{1}{12} = \frac{\Delta_1^2}{24}$

bits	$R$	$D_1$	$D_2$	$D$
0	0	$\sigma^2$	$\sigma^2$	$2\sigma^2$
1	0.5	$\sigma^2/4$	$\sigma^2$	$\frac{5}{4}\sigma^2$
1	0.5	$\sigma^2$	$\sigma^2/4$	$\frac{5}{4}\sigma^2$
2	1	$\sigma^2/4$	$\sigma^2/4$	$\frac{1}{2}\sigma^2$
2	1	$\sigma^2/16$	$\sigma^2$	$\frac{17}{16}\sigma^2$
3	1.5	$\sigma^2/16$	$\sigma^2/4$	$\frac{5}{16}\sigma^2$
4	2	$\sigma^2/16$	$\sigma^2/16$	$\frac{1}{8}\sigma^2$

# Transform coding

Transform: 45-degrees rotation

After the transform the RV are independent

$$f_{Y_1, Y_2}(y_1, y_2) = \begin{cases} \frac{1}{\Delta_1 \Delta_2} & \text{if } (y_1, y_2) \in \mathcal{S} \\ 0 & \text{if } (y_1, y_2) \notin \mathcal{S} \end{cases}$$

$$Y_1 \sim \mathcal{U}\left[-\frac{\Delta_1}{2}, \frac{\Delta_1}{2}\right]$$

$$Y_2 \sim \mathcal{U}\left[-\frac{\Delta_2}{2}, \frac{\Delta_2}{2}\right]$$

# Transform coding

## Example

- ▶ Quantization of  $Y_1$  and  $Y_2$  :  $D(R)$  curve
- ▶  $\sigma_1^2 = \frac{\Delta_1^2}{12} = 2\sigma^2$
- ▶  $\sigma_2^2 = \frac{\Delta_2^2}{12} \ll \sigma^2$

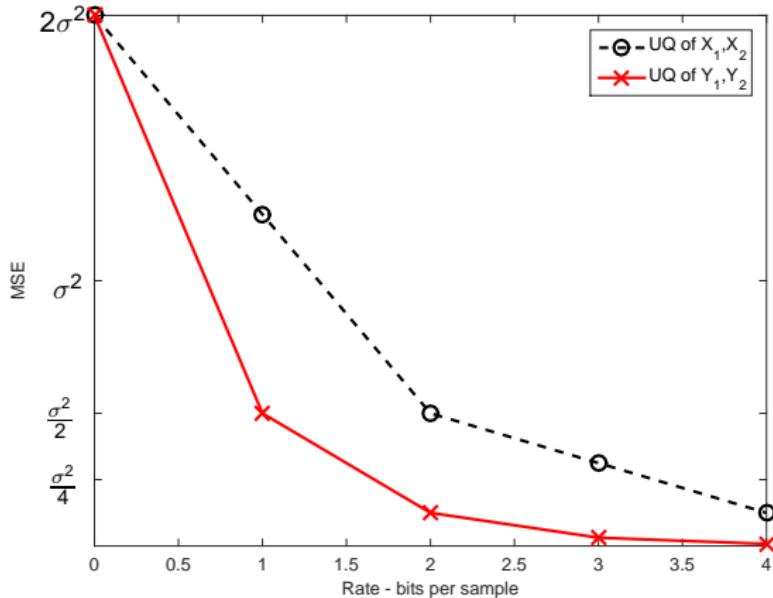

# Transform coding

## Example

- ▶ Quantization of  $Y_1$  and  $Y_2$  :  $D(R)$  curve
- ▶  $\sigma_1^2 = \frac{\Delta_1^2}{12} = 2\sigma^2$
- ▶  $\sigma_2^2 = \frac{\Delta_2^2}{12} \ll \sigma^2$

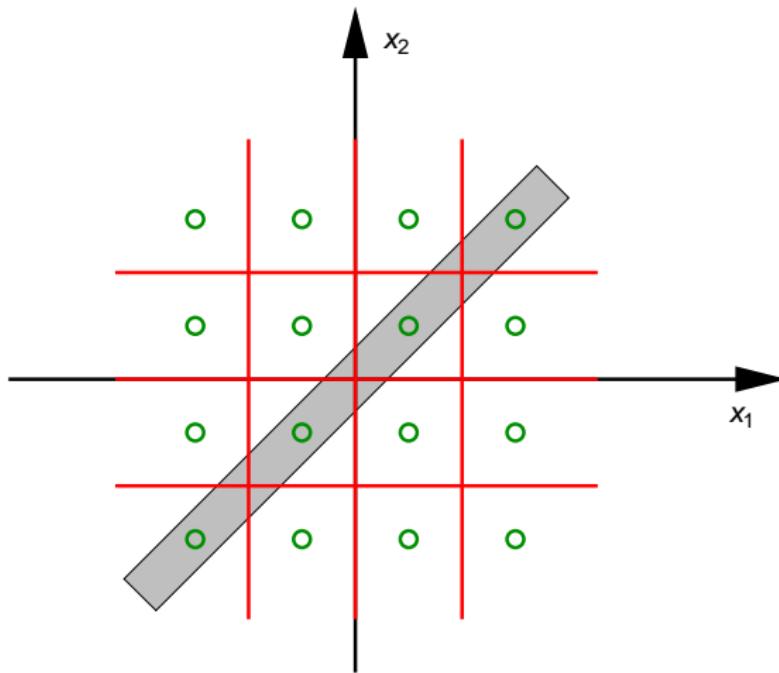

bits	$R$	$D_1$	$D_2$	$D$
0	0	$2\sigma^2$	$\ll \sigma^2$	$2\sigma^2$
1	0.5	$\sigma^2/2$	$\ll \sigma^2$	$\frac{1}{2}\sigma^2$
2	1	$\sigma^2/8$	$\ll \sigma^2$	$\frac{1}{8}\sigma^2$
3	1.5	$\sigma^2/32$	$\ll \sigma^2$	$\frac{1}{32}\sigma^2$

# Transform coding

Quantization regions: VQ

# Plan

Introduction

**Transform coding**

Resource allocation

Discrete cosine transform

JPEG

# Resource allocation

- ▶ Components of  $\mathbf{y} = \mathcal{T}\mathbf{x}$  interpreted as realizations of  $M$  random stationary processes with variances  $\sigma_k^2$
- ▶ Case of orthogonal linear transform:  $\mathcal{T}$  is a square matrix and the distortion is the same in the two domain (original and transformed)

$$\begin{aligned}\mathcal{D} &= E \left[ \| \mathbf{X} - \widehat{\mathbf{X}} \|^2 \right] = E \left[ \| \mathbf{Y} - \widehat{\mathbf{Y}} \|^2 \right] \\ &= E \left[ \sum_{k=0}^{M-1} (Y_k - \widehat{Y}_k)^2 \right] = \sum_{k=0}^{M-1} E \left[ (Y_k - \widehat{Y}_k)^2 \right] \\ &= \sum_{k=0}^{M-1} \mathcal{D}_k\end{aligned}$$

- ▶ We know the relation between  $\mathcal{D}_k$  and the quantization rate  $b_k$  (HR hypothesis) :

$$\mathcal{D}_k = c_k \sigma_k^2 2^{-2b_k}$$

# Resource allocation

## Problem formulation

- ▶ Minimize  $\mathcal{D}$  under a rate constraint

$$\min \mathcal{D}(\mathbf{b}) = \sum_{k=0}^{M-1} c_k \sigma_k^2 2^{-2b_k} \quad \text{subject to} \quad \sum_{k=0}^{M-1} b_k \leq B$$

- ▶ Lagrange method. Minimize:

$$J(\mathbf{b}, \lambda) = \sum_{k=0}^{M-1} c_k \sigma_k^2 2^{-2b_k} + \lambda \left( \sum_{k=0}^{M-1} b_k - B \right)$$

- ▶ Solution (Huang-Schulteiss formula) :

$$b_k^* = \frac{B}{M} + \frac{1}{2} \log \left[ \frac{c_k \sigma_k^2}{c_{GM} \sigma_{GM}^2} \right]$$

# Resource allocations

## Interpretation

- ▶ A uniform resource allocation ( $\bar{b} = B/M$ ) is refined using variances
- ▶ Per-component distortion:

$$\mathcal{D}_k^* = c_k \sigma_k^2 2^{-2b_k^*} = c_k \sigma_k^2 2^{-2\bar{b}} \frac{c_{GM} \sigma_{GM}^2}{c_k \sigma_k^2} = c_{GM} \sigma_{GM}^2 2^{-2\bar{b}}$$

$$\mathcal{D}_{\mathcal{T}} = \sum_{k=0}^{M-1} \mathcal{D}_k^* = M c_{GM} \sigma_{GM}^2 2^{-2\bar{b}}$$

- ▶ Gaussian case:  $c_{GM} = c_k = c_{\mathcal{N}}$  and thus

$$b_k^* = \bar{b} + \frac{1}{2} \log \left[ \frac{\sigma_k^2}{\sigma_{GM}^2} \right] \quad \mathcal{D}_k^* = c_{\mathcal{N}} \sigma_{GM}^2 2^{-2\bar{b}}$$

$$\mathcal{D}_{\mathcal{T}} = M c_{\mathcal{N}} \sigma_{GM}^2 2^{-2\bar{b}}$$

## Coding gain

- ▶ Let  $X$  be a random vector of  $M$  components (sound, image...)
- ▶ Hypothesis :  $X$  components are i.d., e.g. Gaussian  $\mathcal{N}(0, \sigma_X^2)$
- ▶ Without transform, we have SQ and resource allocation. This case is referred to as PCM. The distortion is:

$$\mathcal{D}_{\text{PCM}} = Mc_{\mathcal{N}}\sigma_X^2 2^{-2\bar{b}}$$

# Coding gain

- ▶ The *Coding gain* of  $\mathcal{T}$  the ratio between the PCM distortion and the transform coding distortion:

$$G_{\mathcal{T}} = \frac{\mathcal{D}_{\text{PCM}}}{\mathcal{D}_{\mathcal{T}}} = \frac{\sigma_X^2}{\sigma_{\text{GM}}^2} = \frac{\sigma_{\text{AM}}^2}{\sigma_{\text{GM}}^2}$$

- ▶ The transform should make the vector components as different as possible
- ▶ The geometrical mean of a set of positive numbers is always less or equal than their arithmetical mean

# Resource allocations

## Practical Algorithms

### Huang-Schulteiss' formula

- ▶ might provide negative values
- ▶ might provide non-integer values

### Sub-optimal algorithms

- ▶ Modified HS (Huang-Schulteiss) Algorithm
- ▶ Greedy Algorithm

# Resource allocation

## Modified HS Algorithm

1. We compute  $b_k^*$  with Huang-Schulteiss ;
2. If some  $b_k^*$  are negative, we remove the variances of the concerned components and we repeat the computation.  
The removed variables are not coded (*i.e.*, coded with zero bits)
3. This step is repeated as long as there are negative allocation values.
4. The results are floored
5. The eventual residual rate is allocated to coefficients with the largest error

# Greedy algorithm

## 1. Initialization

- ▶  $b_k = 0 \quad \forall k \in \{0, 1, \dots, M-1\}.$
- ▶  $D_k = \sigma_k^2 \quad \forall k \in \{0, 1, \dots, M-1\}.$

## 2. While $\sum_k b_k \leq B$

- ▶  $\ell = \arg \max_k D_k$
- ▶  $b_\ell \leftarrow b_\ell + 1$
- ▶  $D_\ell \leftarrow D_\ell / 4$

## 2D linear transforms

- ▶ Asymptotically optimal when  $(N, M \rightarrow \infty)$

### DFT

$$t(k, \ell, n, m) = \frac{1}{\sqrt{NM}} \exp \left[ -i 2\pi \left( \frac{(n-1)(k-1)}{N} + \frac{(m-1)(\ell-1)}{M} \right) \right]$$

### DCT

$$t(k, \ell, n, m) = \frac{c_k c_\ell}{\sqrt{NM}} \cos \left( \pi \frac{(2n-1)(k-1)}{2N} \right) \cos \left( \pi \frac{(2m-1)(\ell-1)}{2M} \right)$$

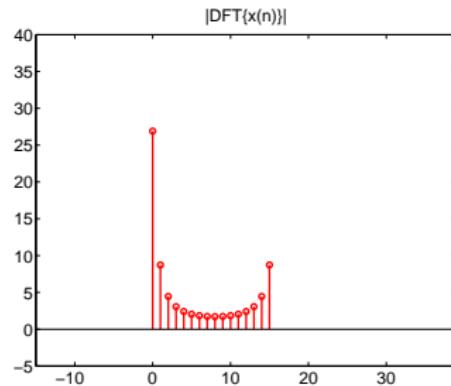

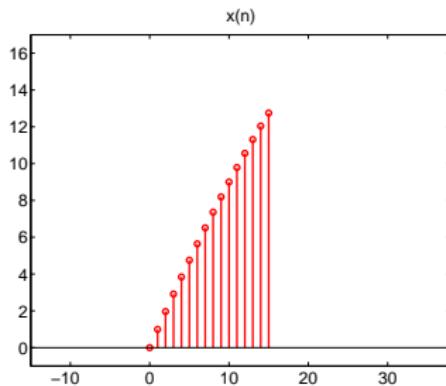

$$c_k = \begin{cases} 1 & \text{si } k = 1 \\ \sqrt{2} & \text{sinon} \end{cases}$$

## 2D linear transforms

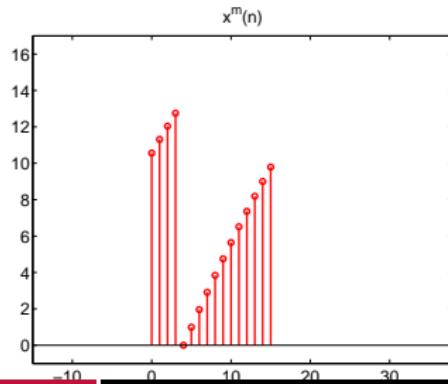

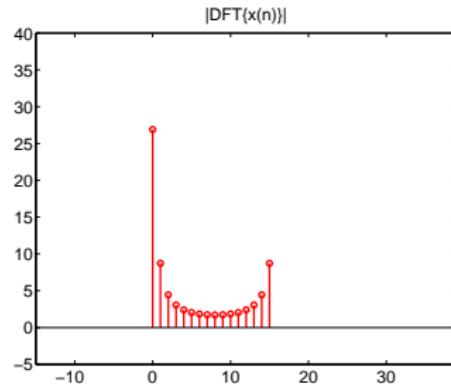

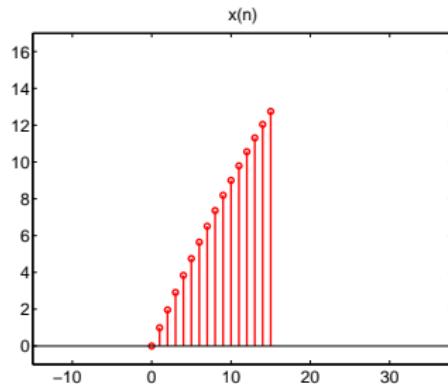

### DCT and DFT

- ▶ Common characteristics
  - ▶ separable :  $t(k, \ell, n, m) = t_1(k, n) t_2(\ell, m)$
  - ▶ fast computations
  - ▶ frequency interpretation
    - $k$  : vertical frequency
    - $\ell$  : horizontal frequency
- ▶ DCT characteristics
  - ▶ Real
  - ▶ Better energy concentration than DFT for images

Introduction

Transform coding

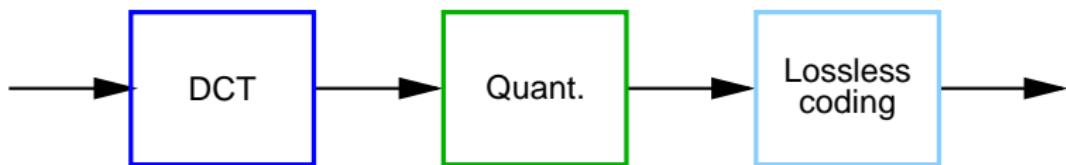

**JPEG**

Principles  
Examples  
Extensions

# JPEG Standard

- ▶ Image compression standard based on DCT
- ▶ Specified in 1991, adopted in 1992
- ▶ It describes *only the decoder*
- ▶ It can work on multi-component (color) images, but we will describe its operation on one component, the other being identical

# JPEG Standard: Scheme

- ▶ The image is decomposed in  $8 \times 8$  pixels blocks
- ▶ The value 128 is subtracted from the image
- ▶ Blocks are (almost) independently encoded

# JPEG Standard: Blocks

Example of 8x8 block

173	171	171	143	109	100	91	96
171	169	150	137	112	101	94	96

# JPEG Standard: Quantization

- ▶ Uniform dead-zone quantization
- ▶  $\tilde{c}_{i,j} = \left\lfloor \frac{c_{i,j}}{q_{i,j}} \right\rfloor$
- ▶ The Quantization  $q$  table defines the RD trade-off, but it is not defined by the standard
- ▶ Thus  $q$  must be encoded
- ▶ Quality factor Q

# JPEG Standard: Quantization

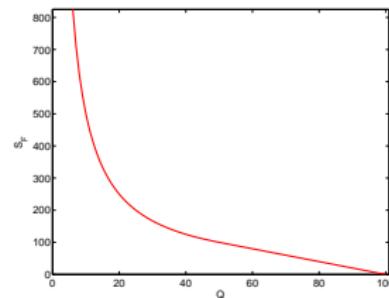

Quantization table example

$$q^* = \begin{array}{|c|c|c|c|c|c|c|c|} \hline 16 & 11 & 10 & 16 & 24 & 40 & 51 & 61 \\ \hline 12 & 12 & 14 & 19 & 26 & 58 & 60 & 55 \\ \hline 14 & 13 & 16 & 24 & 40 & 57 & 69 & 56 \\ \hline 14 & 17 & 22 & 29 & 51 & 87 & 81 & 61 \\ \hline 18 & 22 & 37 & 56 & 68 & 109 & 103 & 77 \\ \hline 24 & 35 & 55 & 64 & 81 & 104 & 111 & 90 \\ \hline 49 & 63 & 78 & 87 & 101 & 121 & 120 & 100 \\ \hline 72 & 92 & 95 & 98 & 112 & 100 & 103 & 99 \\ \hline \end{array}$$

# JPEG Standard:Quality factor

- ▶ Non normative tool
- ▶ Q between 1 and 100
- ▶ Defines a scaling factor  $S_F$  for the quantization matrix

$$S_F = \begin{cases} \frac{5000}{Q} & 1 \leq Q \leq 50 \\ 200 - 2Q & 50 < Q \leq 99 \\ 1 & Q = 100 \end{cases}$$

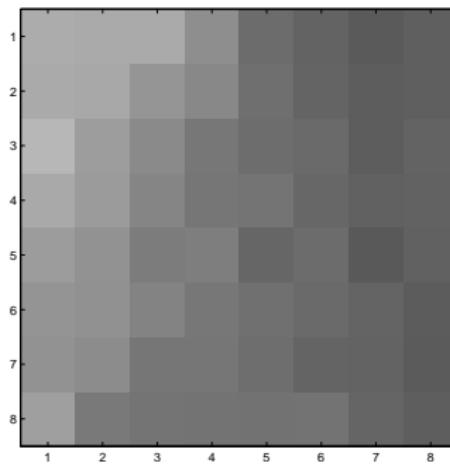

$$q \leftarrow \frac{S_F q^* - 50}{100}$$

# JPEG Standard: Entropy coding

DC Coefficients :

- ▶ represented by the category/amplitude couple
- ▶ There are 12 categories, named 0, ..., 11, coded on 4 bit
- ▶ Category  $k$  contains  $2^k$  values:  $\{\pm 2^{k-1}, \dots, \pm 2^k - 1\}$ ; each value is coded on  $k$  bits

AC Coefficients:

- ▶ represented by run-length, category, amplitude.
- ▶ Categories and run-lengths are coded using a specially designed dictionary, *embedded in the bitstream*
  - ▶ Special symbol 1: (15,0) means “at least 15 zeros before next non-zero coefficient”
  - ▶ Special symbol 2: (0,0) means “end of block”
- ▶ As in the DC case, the category  $k$  contains  $2^k$  values, each coded on  $k$  bits

# JPEG Standard: Parts

- ▶ JPEG baseline (sequential DCT mode)
- ▶ JPEG progressive
- ▶ JPEG hierarchical
- ▶ JPEG sequential lossless mode
- ▶ JPEG part 3
  - ▶ Variable quantization
  - ▶ Tiling
- ▶ JPEG-LS (lossless)
- ▶ Motion JPEG

# JPEG Modes

# Progressive JPEG

## Spectral selection

Example with four quality layers

1. All the DC coefficients
2. The first three AC coefficients of all blocks (zig-zag scan)
3. AC coefficients 4 to 7 of all blocks
4. The other AC coefficients

JPEG syntax allow to define arbitrary layers, provided that they are made up of consecutive transform coefficients in the zig-zag scan order

The quality is the same as baseline JPEG, the rate might be slightly increased.

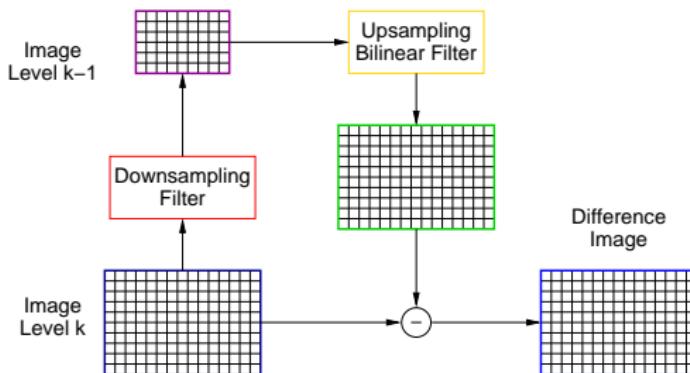

# Progressive JPEG

## Successive approximation

- ▶ First layer : all DC coefficients (as in Spectral Selection)
- ▶ Next layers: bit-plane coding of AC coefficients
  - ▶ An  $8 \times 8$  matrix of coefficients, represented on bits  $\Rightarrow 16$   
 $8 \times 8$  matrices of bits
  - ▶ Entropy coding of bitplanes
- ▶ Increased complexity
- ▶ RD performance slightly improved

# Hierarchical JPEG

## Pyramidal scheme

Each image is coded with baseline or progressive JPEG
